

Web Service Protocols

HTTP: GET, POST, & Friends

GET Requests

- Recall: http offers
 - GET, POST, PUT, DELETE
 - ...plus several more
- Request modification through key/value pairs
 - ?
 - &
- Client sends:

see REST later!

`http://acme.com/srv ? mybasket=6570616275 & article=656e44204456`

Request Parameters: How Passed?

■ GET parameters: URL text

- Can be cached, bookmarked
- Reload / back in history harmless
- Data visible in URL

```
GET srv?k1=v1&k2=v2 HTTP/1.1
```

■ POST parameters: HTTP message body

- Not cached, bookmarked
- Reload / back in history **re-submits**
- Data not visible,
not in history,
not in server logs

```
POST srv HTTP/1.1
```

```
k1=v1&k2=v2
```

http://www.w3schools.com/tags/ref_httpmethods.asp

REST

(Representational State Transfer)

REST

[Thomas Roy Fielding, 2002]

- REST
 - = Representational State Transfer
 - Resource + URI
 - *Web = one address space*
 - representation
 - Client requests follow xlink
 - *→ new state*
- Not a standard nor product, but „**architectural style**“
 - = way to craft Web interface
- URI defines resource being requested
 - Consistent design philosophy
 - easy to follow
- Relies on four basic http operations:
 - GET – *Query*
 - POST – *Update*
 - PUT – *Add*
 - DELETE – *Delete*

Sample RESTful Application

- *Scenario: online shop*
- Fetch information: "shopping basket with id 5873" GET /shoppingBasket/5873

- Response:

```
<shoppingBasket xmlns:xlink="http://www.w3.org/1999/xlink">
  <customer xlink:href="http://shop.oio.de/customer/5873">5873</customer>
  <position nr="1" amount="5">
    <article xlink:href="http://shop.oio.de/article/4501" nr="4501">
      <description>lollypop</description>
    </article>
  </position>
  <position nr="2" amount="2">... </position>
</shoppingBasket>
```

- Client can follow links, that changes its state
- No side effect (status change) on server side

Sample RESTful Application (contd.)

- Place order:

"add article #961 to shopping basket #5873"

- Changes server state

```
POST /shoppingBasket/5873
articleNr=961
```

- Add article

- Again, changes server state
- Returns new id

```
PUT /article
```

```
<article>
  <description>Rooibush tea</description>
  <price>2.80</price>
  ...
</article>
```

```
HTTP/1.1 201 OK
```

```
...
```

```
http://shop.oio.de/article/6005
```

- Delete article

- Server state change

```
DELETE /article/6005
```

Choice of Return Formats

- Problem: how to indicate output format
 - Ex: Old browsers understood GIF, JPEG for imagery
 - GET/KVP: `http://.../service-endpoint?q=...&format=image/tiff`
- REST: use http **Accept-Encoding** parameter [IETF RFC 2616]
 - More powerful than GET: negotiate **alternatives**, **quality factor** $q \in [0..1]$
 - However, RESTafarians typically ignore this, use „...&f=...“ ...back to GET/KVP ;-)
- Examples:
 - Accept-Encoding: **compress, gzip**
 - Accept-Encoding:
 - Accept-Encoding: *****
 - Accept-Encoding: **compress;q=0.5, gzip;q=1.0**
 - Accept-Encoding: **gzip;q=1.0, identity; q=0.5, *;q=0**

Security

- Remember: SOAP, XML-RPC do http tunneling
 - Major security leak:
 - cannot determine request payload unless body is inspected and understood (!)
- REST: typed requests, firewall can judge → better security

```
hermes.oio.de - - [26/Nov/2002:12:43:07 +0100] "GET /shoppingBasket/6 HTTP/1.1" 200
hermes.oio.de - - [26/Nov/2002:12:43:08 +0100] "GET /article/12 HTTP/1.1" 200
hermes.oio.de - - [26/Nov/2002:12:43:08 +0100] "GET /article/5 HTTP/1.1" 200
hermes.oio.de - - [26/Nov/2002:12:43:09 +0100] "POST /shoppingBasket/6 HTTP/1.1" 200
hermes.oio.de - - [26/Nov/2002:12:43:13 +0100] "POST /shoppingBasket/6 HTTP/1.1" 200
hermes.oio.de - - [26/Nov/2002:12:43:14 +0100] "GET /Order/3 HTTP/1.1" 200
```

- → *admins much more inclined to open firewall for REST services than for SOAP*

REST: How Powerful?

- Local **path** uses historical directory syntax → strict **hierarchy**
 - `http://.../service-endpoint/MyShop/ShoppingBaskets/14731/Article/67236`
 - Standard Web servers, proxies etc can **cache**

- What breaks hierarchies
 - Multi-dimensional indexing – *Lat/Long/height/time has no particular sequence*
 - SQL: joins – *join tables come in no particular sequence*
 - SQL: complex predicates – *.../filter1/filter2/filter3/... cannot express AND / OR / NOT*
 - SQL: nested queries

- Remedy: old-school KVP `http://.../service-endpoint/MyShop?q=select-from-where`
 - So much more powerful, but no caching etc.

REST: Appraisal

■ Strengths

- Simple paradigm; Web = RESTful resource *(SOAP: individual spec per service)*
- Caching *(SOAP: based on POST, not cached)*
- Proven base stds: http, URI, MIME, XML *(SOAP: WSDL, UDDI, WS-*, BPEL, ...)*
 - *Oops: cookies break REST paradigm*

■ Weaknesses

- Assumes addressability by path + identifier (URI!) = single-root hierarchies
→ only fraction of SQL power
- Schema to represent all URIs is complex
- response data structure definition outside REST *(how was that with SOAP?)*
- limited support for HTTP PUT & DELETE in popular development platforms
- Power of http headers not accessible via browser URL

Summary

- Web services: want function invocation on server
 - Remote Procedure Call (RPC)
 - Existing since 1980s: XDR

- Web World is evolving
 - New paradigms emerging (and some disappearing)
 - GET/KVP, POST/XML, SOAP, REST, JSON, OpenAPI, ...

- Service protocol independent from database query languages!
 - Ex:
 - *GET/KVP*: `http://acme.com/access-point?q=select%20*%20from...`
 - *POST/XML*: `<query>select *from...</query>`

AJAX

(Asynchronous Javascript and XML)

History

- Challenge: want **more interactivity** than "click link / reload *complete page*"
 - HTML's `iframes`
- Microsoft IE5 XMLHttpRequest object
 - Outlook Web Access, supplied with Exchange Server 2000
- 2005: term "AJAX" coined by Jesse James Garnett
- made popular in 2005 by Google Suggest
 - start typing into Google's search box → list of suggestions

AJAX

- **AJAX = Asynchronous Javascript and XML**
- **web development technique for creating more interactive web applications**
 - Goal: increase interactivity, speed, functionality, usability
 - not complete page reload → small data loads → more responsive
- **asynchronous: c/s communication independent from normal page loading**
 - JavaScript
 - XML
 - any server-side PL

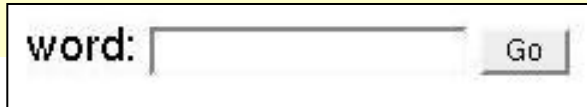

AJAX Constituent Technologies

- The core: JavaScript **XMLHttpRequest** object
 - Sends data, waits for response via event handler
 - Replaces <FORM> and HTTP GET / POST
- **Client DOM manipulated** to dynamically display & interact
 - Inject response into any place(s) of DOM tree
 - client-side scripting language: JavaScript, Jscript, ...
- Some data format
 - XML, JSON, HTML, text, ...
- Some server agent
 - Servlet, script, ...

Ajax Example: Traditional Style

- Client:

```
<form method='GET' action='http://.../ajax-ex.php'>
  word:
  <input name='wordKey' type='text'>
  <input type='submit' value='Go'>
</form>
```

word:

- Server:

```
<?
  echo 'You have entered ' . $_GET['wordKey']
    . ' and your IP is: ' . $_SERVER['REMOTE_ADDR'];
?>
```

- Client, after **page reload**: You have entered Moribundus, and your IP is: 127.0.0.1

Step 1: Avoid Complete Page Reload

```
<form name='wordForm'>
  word:
  <input name='wordKey' type='text'>
  <input type='button' value='Go' onClick='JavaScript:callback()'>
  <div id='result'></div>
</form>
```

```
function callback()
{
  var SERVICE = 'http://.../ajax-ex.php';
  var req = new XMLHttpRequest();
  var val = document.forms['wordForm'].wordKey.value;
  req.open( 'GET', SERVICE+'?wordKey='+val, true );
  req.setRequestHeader( 'Content-Type',
                      'application/x-www-form-urlencoded' );
  req.send( null );
  req.onreadystatechange = function()
  {
    if (req.readyState == 4)
      document.forms['wordForm'].result.innerHTML =
        req.responseText;
  }
}
```

- 0 request not initialized
- 1 request set up
- 2 request sent
- 3 request in process
- 4 request complete

word: _____

You have entered Moribundus, and your IP is: 127.0.0.1

Step 2: Avoid SUBMIT Button

- Before: just re-implemented submit; now: allow c/s activity at **any time**
 - Event handlers
- Ex: suggest keywords with every char typed
 - No submit button!

The screenshot shows a web form with the following elements:

- Abflughafen:** A text input field containing the text "bre".
- Zielflughafen:** A dropdown menu showing a list of airport suggestions: "Bremen (BRE) Deutschland", "Brescia (VBS) Italien", "Breslau (WRO) Polen", and "Brest (BES) Frankreich".
- Nur Hinflug:** A checkbox that is currently unchecked.

`<input name='wordKey' onKeyUp='JavaScript:callBack()' >`

```
<? ...
$query = "select entry from Airports
         where entry like '" . $_GET['wordKey'] . "%'";
$result = mysql_query( $query );
while ( $row = mysql_fetch_array( $result ) )
{
    print $row[ 'entry' ] . ",";
}
?>
```

*How to ship back
& inject data?*

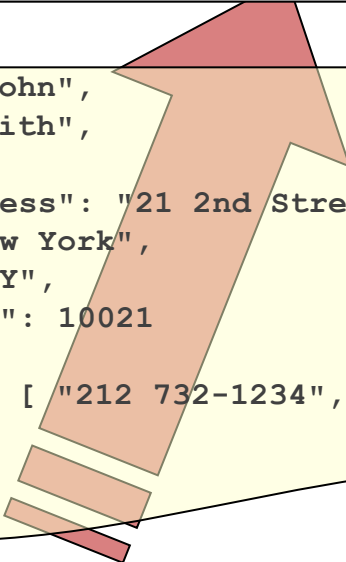

Step 3: Selective Page Update

- Server sends:

```
req.onreadystatechange=function()
{
  if(req.readyState==4)
  {
    var p = eval( "(" + req.responseText + ")" );
    document.myForm.firstName.value = p.firstName;
  }
}
```

- JSON string sent from server:

```
{
  "firstName": "John",
  "lastName": "Smith",
  "address":
  {
    "streetAddress": "21 2nd Street",
    "city": "New York",
    "state": "NY",
    "postalCode": 10021
  },
  "phoneNumbers": [ "212 732-1234", "646 123-4567" ]
}
```

- response parsing code:

```
<? echo '{' + '"firstName":' + obj.firstName + ',' +
      + '"lastName":' + obj.lastName + ',' +
      ... + '}'
?>
```

JSON Security Concerns

- JavaScript `eval ()`
 - most JSON-formatted text is also **syntactically legal JavaScript code!**
 - built-in JavaScript `eval ()` function **executes** code received

- **Invitation to hack:**
 embed rogue JavaScript code (server-side attack),
 intercept JSON data evaluation (client-side attack)
 - **Safe alternative:** `parseJSON ()` method,
 see ECMAScript v4 and www.json.org/json.js

- Cross-site request forgery
 - malicious page can request & obtain JSON data belonging to another site

AJAX / JSON Portability

- AJAX uses **standardized components**, supported by all major browsers:
 - JavaScript, XML, HTML, CSS
- XMLHttpRequest object part of **std DOM**
 - Windows: ActiveX control Msxml2.XMLHTTP (IE5), Microsoft.XMLHTTP (IE6)
- ...similarly for JSON

Sample Tool Support: jQuery

- JavaScript library, <http://jquery.com>
- Code examples:

```
$( "button.continue" ).html( "Next Step..." )
```

```
$.ajax({  
  url: "/api/getWeather",  
  data: {  
    zipcode: 97201  
  },  
  success: function( data ) {  
    $( "#weather-temp" ).html( "<b>" + data + "</b> degrees" );  
  }  
});
```

Appraisal: AJAX Advantages

- Reduced **bandwidth usage**
 - No complete reload/redraw, HTML generated locally, only actual data transferred
→ payload coming down much smaller in size
 - Can load stubs of event handlers, then functions on the fly
- **Separation** of data, format, style, and function
 - encourages programmers to clearly separate methods & formats:
 - Raw data / content → normally embedded in XML
 - webpage → HTML / XHTML
 - web page style elements → CSS
 - Functionality → JavaScript + XMLHttpRequest + server code

Appraisal: AJAX Disadvantages

- **Browser integration**
 - dynamically created page not registered in browser history
 - bookmarks
- **Search engine optimization**
 - Indexing of Ajax page contents?
 - (not specific to Ajax, same issue with all dynamic data sites)
- **Web analytics**
 - Tracking of accessing page vs portion of page vs click?
- **Response time concerns from network latency**
 - Web transfer hidden → effects from delays sometimes difficult to understand for users
- **Reliance on JavaScript**
 - JavaScript compatibility issue → blows up code; Remedy: libraries such as `prototype`
 - IDE support used to be poor, changing
 - Can switch off JavaScript in my browser
- **Security**
 - Can fiddle with data getting into browser

Summary

- AJAX allows to add desktop flavour to web apps
 - JSON as lightweight, fast alternative to XML
- Web programming paradigm based on existing, available standards
- Issues: browser compatibility, security, web dynamics
- Manifold usages:
 - real-time form data validation; autocompletion; bg load on demand; sophisticated user interface controls and effects (trees, menus, data tables, rich text editors, calendars, progress bars, ...); partial submit; mashups (app mixing); desktop-like web app

AJAX

(Asynchronous Javascript and XML)

History

- Challenge: want **more interactivity** than "click link / reload *complete page*"
 - HTML's `iframes`
- Microsoft IE5 XMLHttpRequest object
 - Outlook Web Access, supplied with Exchange Server 2000
- 2005: term "AJAX" coined by Jesse James Garnett
- made popular in 2005 by Google Suggest
 - start typing into Google's search box → list of suggestions

AJAX

  echo 'You have entered ' . $_GET['wordKey']
    . ' and your IP is: ' . $_SERVER['REMOTE_ADDR'];
?>
```

- Client, after **page reload**: You have entered Moribundus, and your IP is: 127.0.0.1

Step 1: Avoid Complete Page Reload

```
<form name='wordForm'>
  word:
  <input name='wordKey' type='text'>
  <input type='button' value='Go' onClick='JavaScript:callback()'>
  <div id='result'></div>
</form>
```

```
function callback()
{
  var SERVICE = 'http://.../ajax-ex.php';
  var req = new XMLHttpRequest();
  var val = document.forms['wordForm'].wordKey.value;
  req.open( 'GET', SERVICE+'?wordKey='+val, true );
  req.setRequestHeader( 'Content-Type',
                      'application/x-www-form-urlencoded' );
  req.send( null );
  req.onreadystatechange = function()
  {
    if (req.readyState == 4)
      document.forms['wordForm'].result.innerHTML =
        req.responseText;
  }
}
```

- 0 request not initialized
- 1 request set up
- 2 request sent
- 3 request in process
- 4 request complete

word: _____

You have entered Moribundus, and your IP is: 127.0.0.1

Step 2: Avoid SUBMIT Button

- Before: just re-implemented submit; now: allow c/s activity at **any time**
 - Event handlers
- Ex: suggest keywords with every char typed
 - No submit button!

`<input name='wordKey' onKeyUp='JavaScript:callBack()' >`

```
<? ...
$query = "select entry from Airports
         where entry like '" . $_GET['wordKey'] . "%'";
$result = mysql_query( $query );
while ( $row = mysql_fetch_array( $result ) )
{
    print $row[ 'entry' ] . ",";
}
?>
```

*How to ship back
& inject data?*

JSON

- JSON = **JavaScript Object Notation**
 - Lightweight data interchange format
 - MIME type: `application/json` (RFC 4627)
 - text-based, human-readable
- alternative to XML use
 - Subset of JavaScript's object literal notation
 - 10x faster than XML parsing
 - way easier to handle
 - JSON parsing / generating code readily available for many languages

"JSON is XML without garbage"

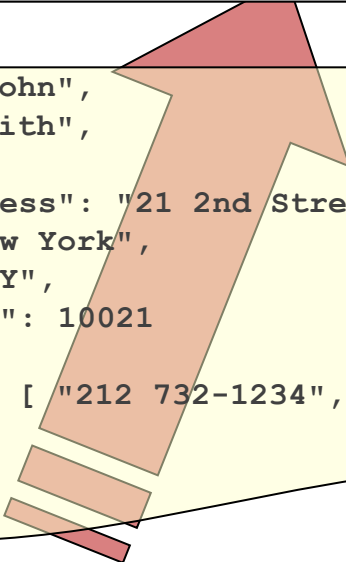

JSON Example

- Server sends:

```
req.onreadystatechange=function()
{
  if(req.readyState==4)
  {
    var p = eval( "(" + req.responseText + ")" );
    document.myForm.firstName.value = p.firstName;
  }
}
```

- JSON string sent from server:

```
{
  "firstName": "John",
  "lastName": "Smith",
  "address":
  {
    "streetAddress": "21 2nd Street",
    "city": "New York",
    "state": "NY",
    "postalCode": 10021
  },
  "phoneNumbers": [ "212 732-1234", "646 123-4567" ]
}
```

- response parsing code:

```
<? echo '{' + '"firstName":' + obj.firstName + ',' +
      + '"lastName":' + obj.lastName + ',' +
      ... + '}'
?>
```

JSON Security Concerns

- JavaScript `eval ()`
 - most JSON-formatted text is also **syntactically legal JavaScript code!**
 - built-in JavaScript `eval ()` function **executes** code received

- **Invitation to hack:**
 embed rogue JavaScript code (server-side attack),
 intercept JSON data evaluation (client-side attack)
 - **Safe alternative:** `parseJSON ()` method,
 see ECMAScript v4 and www.json.org/json.js

- Cross-site request forgery
 - malicious page can request & obtain JSON data belonging to another site

AJAX / JSON Portability

- AJAX uses **standardized components**, supported by all major browsers:
 - JavaScript, XML, HTML, CSS
- XMLHttpRequest object part of **std DOM**
 - Windows: ActiveX control Msxml2.XMLHTTP (IE5), Microsoft.XMLHTTP (IE6)
- ...similarly for JSON

Appraisal: AJAX Advantages

- Reduced **bandwidth usage**
 - No complete reload/redraw, HTML generated locally, only actual data transferred
→ payload coming down much smaller in size
 - Can load stubs of event handlers, then functions on the fly

- **Separation** of data, format, style, and function
 - encourages programmers to clearly separate methods & formats:

Raw data / content	→ normally embedded in XML
webpage	→ HTML / XHTML
web page style elements	→ CSS
Functionality	→ JavaScript + XMLHttpRequest + server code

Appraisal: AJAX Disadvantages

- **Browser integration**
 - dynamically created page not registered in browser history
 - bookmarks
- **Search engine optimization**
 - Indexing of Ajax page contents?
 - (not specific to Ajax, same issue with all dynamic data sites)
- **Web analytics**
 - Tracking of accessing page vs portion of page vs click?
- **Response time concerns from network latency**
 - Web transfer hidden → effects from delays sometimes difficult to understand for users
- **Reliance on JavaScript**
 - JavaScript compatibility issue → blows up code; Remedy: libraries such as `prototype`
 - IDE support used to be poor, changing
 - Can switch off JavaScript in my browser
- **Security**
 - Can fiddle with data getting into browser

Tool Support: Examples

- jQuery, <http://jquery.com/>

```
$( "button.continue" ).html( "Next Step..." )
```

- AJAX:

```
$.ajax({  
  url: "/api/getWeather",  
  data: {  
    zipcode: 97201  
  },  
  success: function( data ) {  
    $( "#weather-temp" ).html( "<b>" + data + "</b> degrees" );  
  }  
});
```

Kore rawa e rawaka te reo kotahi
