

Relational Algebra

Molina, Ullman, Widom

Database Management: Complete Book, Chapters 2 & 5

What is “Algebra”?

- Mathematical system consisting of:
 - **Operands** - variables or values from which new values can be constructed
 - **Operators** - symbols denoting procedures that construct new values from given values
 - Ex: $((x + 7)/(2 - 3)) + x$
- **Algebra** $A = (C, OP)$
 - "simplest" mathematical structure:
 - C nonempty **carrier set** (=value set)
 - OP nonempty **operation set**
 - C **closed** under OP expressions

Algebra

- 2 "fathers of algebra":
 - where algebra $\equiv$ theory of equations
→ Greek *Diophantus*
 - where algebra $\equiv$ rules for manipulating & solving equations
→ Persian *al-Khwarizmi*

Selection

- $R1 := \sigma_C(R2)$
 - C : condition on attributes of $R2$.
 - $R1$ is all those tuples of $R2$ that satisfy C .

sid	name	login	gpa
53666	Jones	jones@cs	3.4
53688	Smith	smith@eecs	3.2
53650	Smith	smith@math	3.8

$\sigma_{\text{gpa} < 3.8}(\text{Students})$:

sid	name	login	gpa
53666	Jones	jones@cs	3.4
53688	Smith	smith@eecs	3.2

Selection: Observations

- unary operation: 1 table
- conditions apply to each tuple individually
 - condition cannot span tuples (how to do that?)
- degree of $\sigma_C(R)$ = degree of R
 - Cardinality?
- Select is commutative: $\sigma_{C_1}(\sigma_{C_2}(R)) = \sigma_{C_2}(\sigma_{C_1}(R))$
 - Ex: $\sigma_{S.sid=E.sid}(\sigma_{E.cid=C.cid}(R)) = \sigma_{E.cid=C.cid}(\sigma_{S.sid=E.sid}(R))$

Projection

- $R1 := \pi_{attr}(R2)$
 - *attr* : list of attributes from R2 schema
- For each tuple of R2:
 - extract attributes from list *attr* in order specified (!) → R1 tuple
- Eliminate duplicate tuples

sid	name	login	gpa

53666	Jones	jones@cs	3.4
53688	Smith	smith@eecs	3.2
53650	Smith	smith@math	3.8

$\pi_{name,login}(Students) =$

name	login

Jones	jones@cs
Smith	smith@eecs

Projection: Observations

- Unary operation: 1 table
- removes duplicates in result
 - Cardinality?
 - Degree?
- Project is **not** commutative
- Sample algebraic law: $\pi_{L_1} (\pi_{L_2}(R)) = \pi_{L_1}(R)$ if $L_1 \subseteq L_2$
 - else incorrect expression, syntax error
 - Ex: $\pi_{\text{name}} (\pi_{\text{name,gpa}}(R)) = \pi_{\text{name}}(R)$

Cross Product

- project, select operators operate on **single** relation
- Cartesian product combines **two**: $R3 = R1 \times R2$
 - Pair each tuple $t1 \in R1$ with each tuple $t2 \in R2$
 - Concatenation $(t1, t2)$ is a tuple of $R3$
 - Schema of $R3$ = attributes of $R1$ and then $R2$, in order
- Algebraic laws? Associative; commutative if ignoring attribute order; ...

Cross Product (“Cartesian Product”)

- Example $U := R \times S$

A	B
1	2
3	4

(a) Relation R

B	C	D
2	5	6
4	7	8
9	10	11

(b) Relation S

A	$R.B$	$S.B$	C	D
1	2	2	5	6
1	2	4	7	8
1	2	9	10	11
3	4	2	5	6
3	4	4	7	8
3	4	9	10	11

(c) Result $R \times S$

Natural Join

- $T = R \bowtie S$

- Ex: Reserves $\bowtie_{bid}$ Sailors

„natural“ = remove
duplicate attribute(s)

- connect **two** relations:

- Equate attributes of **same name**, **project out** redundant attribute(s)

<i>A</i>	<i>B</i>
1	2
3	4

(a) Relation *R*

<i>B</i>	<i>C</i>	<i>D</i>
2	5	6
4	7	8
9	10	11

(b) Relation *S*

<i>A</i>	<i>R.B</i>	<i>S.B</i>	<i>C</i>	<i>D</i>
1	2	2	5	6
1	2	4	7	8
1	2	9	10	11
3	4	2	5	6
3	4	4	7	8
3	4	9	10	11

(c) Result $R \times S$

<i>A</i>	<i>B</i>	<i>C</i>	<i>D</i>
1	2	5	6
3	4	7	8

$R \bowtie S$

Relational Algebra: Summary

= Mathematical definition of relations + operators

- Query = Algebraic expression
- **Relational algebra** $A = (R, OP)$ with relation $R = A_1 \times \dots \times A_n$, $OP = \{\pi, \sigma, \times\}$
 - **Projection**: $\pi_{attr}(R) = \{ r.attr \mid r \in R \}$
 - **Selection**: $\sigma_p(R) = \{ r \mid r \in R, p(r) \}$
 - **Cross product**: $R_1 \times R_2 = \{(r_{11}, r_{12}, \dots, r_{21}, r_{22}, \dots) \mid (r_{11}, r_{12}, \dots) \in R_1, (r_{21}, r_{22}, \dots) \in R_2\}$
 - Further: set operations, join, ...
- Set + predicate notation = **Relational Calculus**
 - Equally powerful as Relational Algebra – proven by E Codd

Relational Calculus

- **Tuple variable** = variable over some relation schema
- **Query** $Q = \{ T \mid T \in R, p(T) \}$
 - R relation schema, p(T) predicate over T
- **Example 1: "sailors with rating above 8"**
 - Sailors = $\text{sid:int} \times \text{sname:string} \times \text{rating:int} \times \text{age:float}$
 - = $\{ S \mid S \in \text{Sailors} \wedge S.\text{rating} > 8 \}$
- **Example 2: "names of sailors who have reserved boat #103":**
 - Reserves = $\text{sid:int} \times \text{bid:int} \times \text{day:date}$
 - = $\{ S.\text{sname} \mid \exists S \in \text{Sailors} \exists R \in \text{Reserves}: R.\text{sid} = S.\text{sid} \wedge R.\text{bid} = 103 \}$

Comparison of Relational Math

- Relational **algebra**
 - set-based formalization of selection, projection, cross product (no aggregation!)
 - Operation oriented = procedural = **imperative**; therefore basis of optimization
- Relational **calculus**
 - Same, but in predicate logic
 - Describing result = **declarative**; therefore basis of SQL semantics
- **Equally powerful**
 - proven by E Codd in 1970
